Extended Data Fig. 1	Extended Data Fig. 1	EF1.pdf	a-c) GO enrichment analysis of upregulated differentially expressed genes from unstimulated vs. <i>C. albicans</i> - stimulated ILC3 subsets including cILC3s (related to Figure 2a) (a); MHCII ⁺ ILC3s (related to Figure 2b) (b); Aire ⁺ ILC3s (related to Figure 2c) (c). d) Heatmap of Pearson correlation according to gene expression values between individual samples analyzed in Fig. 2a-c.
Extended Data Fig. 2	Extended Data Fig. 2	EF2.pdf	a) Imaging flow cytometry analyzing the physical interaction between HKCA with DCs or with Aire ⁺ ILC3s. CD11c ⁺ DCs or Lineage negative cells and were isolated from mouse popliteal lymph nodes using MACS-beads depletion and then incubated with CPD-stained HKCA for 90 minutes. Samples were stained for Aire, MHCII, CD11c, Lamp1 (lysosomal marker) and DAPI and analyzed by Imaging flow cytometry. In both, Aire ⁺ ILC3 cells (Aire ⁺) and DCs (CD11c ⁺) HKCA associate with lysosomes (Lamp1). Representative images out of five independent repetitions of the experiment are shown. (b) Comparison of the capacity of different immune subsets (B cells, Ly6C ⁺ MNPs, CD11b ⁺ MNPs, CD11c ⁺ MNPs and Aire ⁺ ILC3s) to endocytose CPD-labeled HKCA in an in-vitro endocytosis assay. Subsets were FACS-sorted and incubated with HKCA-CPD for three hours. The frequency of cells that have successfully internalized HKCA-CPD was then assessed by flow cytometry (mean ± SD; n=3). c-d) Comparison of the capacity of either wild-type or Galectin-3/Dectin-1-double knockout (dKO) Aire ⁺ ILC3s (c) or DCs (d) to endocytose CPD-labeled HKCA at 37°C or at 4°C. Corresponding populations were isolated from WT or dKO mice and kept either at 37°C or at 4°C. The internalization of HKCA-CPD by the cells was measured by FACS (mean ± SD; n=3). e) Representative gating

			<p>strategy of APC populations related to Fig. 3c-g. f) FACS analysis of in vitro assay related to Fig. 3c. g) Graphical summary of an experimental setting relevant for data shown in h. Wild-type mice were intravenously stimulated HKCA in specified timepoints and APC population were isolated using gating strategy depicted in e. h) FACS analysis of in vitro assay related to Fig. 3d-f assessing the antigen presentation of the corresponding cell subsets.</p>
Extended Data Fig. 3	Extended Data Fig. 3	EF3.pdf	<p>a) FACS analysis validating that Aire protein expression in the entire LN-resident cell compartment is exclusively restricted to a CD45 positive, lineage negative (Lin 1: TCR-β, CD19, Gr-1, F4/80, CD11b, CD11c, NK1.1; Lin 2: CD3, B220), NKp46-negative, MHCII positive, Rorγt positive cell subset – previously identified as Aire⁺ ILC3s. b) Back-gating FACS analysis of Aire-expressing cells identified in a. c) Representative flow cytometry dot plots showing the frequencies of transferred CD45.1⁺ OT-II T cell (red gate) vs. CD45.1/CD45.2 double positive control T cell (blue gate) populations 2 days after the transfer. d) Statistical analysis of ratios related to b (n=5 per group, mean \pm SD, two-tailed Student's t-test) of OT-II vs. control T two days after the transfer. e-f) Survival curves of WT (Aire^{+/+}) and knockout (Aire^{-/-}) mice (n\geq10 mice per group) on either on NOD (e) and C57Bl/1 (f) genetic background after systemic challenge with live <i>C. albicans</i>. Mice were <i>i.v.</i> injected every second day by heat-killed <i>C. albicans</i> (HKCA) for the duration of three weeks. Subsequently, mice were infected by alive <i>C. albicans</i> and monitored for survival. Long-rank (Mantel-Cox) test was used to calculate the indicated p-value. g-h) Quantitative PCR analysis assessing the presence of <i>C. albicans</i>-specific DNA in the liver (g) and small intestine (h) from <i>Rorc</i>-Cre⁻ Aire^{fl/fl} (WT) and <i>Rorc</i>-Cre⁺ Aire^{fl/fl} (ILC3ΔAire) mice (n=6, mean \pm SD, two-tailed Student's t-test). i-j) ELISA assessing the amount of IL-17 (i) or (IL-22) (j) autoantibodies in the sera of 8-week old untreated Aire^{+/+} vs. Aire^{-/-} mice on NOD and C57Bl/6 (B6) genetic background (n=6 per group, two-tailed Student's t-test). Data are shown as mean of optical density \pm SD. Data are</p>

40 **ABSTRACT**

41

42 Patients with loss of function in the gene encoding the master regulator of central tolerance *AIRE*
43 suffer from a devastating disorder called autoimmune polyendocrine syndrome type 1 (APS-1),
44 characterized by a spectrum of autoimmune diseases and severe mucocutaneous candidiasis. While
45 the key mechanisms underlying the development of autoimmunity in APS-1 patients are well-
46 established, the underlying cause for the increased susceptibility to *Candida albicans* infection
47 remains less understood. Here we show that Aire⁺MHCII⁺ type-3 innate lymphoid cells (ILC3)
48 could sense, internalize and present *Candida albicans*, and had a critical role in the induction of
49 candida-specific T_H17 cell clones. Extrathymic *Rorc*-Cre-mediated deletion of *Aire* resulted in
50 impaired generation of candida-specific T_H17 cells and subsequent overgrowth of *C. albicans* in
51 the mucosal tissues. Collectively, our observations identify a previously uncharacterized regulatory
52 mechanism for effective defense responses against fungal infections.

53

54 The transcriptional regulator Aire has an essential role in the induction of self-tolerant T cells
 55 during thymic development by controlling the expression of thousands of self-antigen genes in
 56 medullary thymic epithelial cells (mTECs)^{1,2}. Presentation of self-antigens by mTECs is essential
 57 for the deletion of self-reactive T cell clones³ or their conversion into regulatory T cells (T_{reg} cells)
 58 ^{4,5}. *Aire* deficiency results in impaired T_{reg} cell generation and escape of self-reactive T cells into
 59 the periphery, leading to breakdown of immunological tolerance to various parenchymal tissues¹.

60 Patients with *AIRE* deficiency develop a rare genetic disorder called autoimmune polyendocrine
 61 syndrome type-1 (APS-1; also known as autoimmune polyendocrinopathy candidiasis ectodermal
 62 dystrophy – APECED, OMIM: 240300), which is characterized by autoimmune pathologies such
 63 as hypoparathyroidism and primary adrenocortical insufficiency (Addison's disease), with
 64 additional autoimmune disorders such as hypothyroidism, type-1 diabetes, premature ovarian
 65 failure, pernicious anemia, vitiligo, alopecia, keratitis or intestinal malabsorption occurring with
 66 lower frequency ^{6,7}. In addition, the vast majority (75-100%) of APS-1 patients develop chronic
 67 mucocutaneous candidiasis (CMC), mainly characterized by *C. albicans* overgrowth in the oral
 68 cavity, esophagus and nails as early as 1 year of age (median 5 years) ^{8,9}. Because candidiasis is
 69 a common complication in people born with a loss of function mutation in various genes linked to
 70 the CD4⁺ helper type 17 (T_H17 cell)-mediated response (e.g. *RORC*¹⁰, *IL17F*¹¹, *STAT3*¹²,
 71 *CLEC7A*¹³, *CARD9*¹⁴ or *STAT1*¹⁵), T_H17 cells are assumed to have an indispensable role in long
 72 term protection against *C. albicans* infection¹⁶. APS-1 patients have been reported to develop
 73 autoantibodies against the T_H17 effector cytokines IL-17A, IL17-F and/or IL-22^{17,18}, suggesting
 74 that the increased susceptibility to *C. albicans* might also be caused by an autoimmune-mediated
 75 mechanism. However, a considerable fraction of APS-1 patients with very low or no IL-17 or IL-
 76 22 autoantibodies still develop CMC^{17,18}, indicating the correlation between the IL-17- and/or IL-
 77 22-specific autoantibodies and candidiasis is incomplete and that additional mechanism(s) may be
 78 involved.

79 In addition to its well-established expression pattern in the thymus, Aire was reported to be
80 expressed in a rare population of cells residing in the lymph nodes (LNs) and bearing the hallmarks
81 of a subset of MHCII⁺ type-3 innate lymphoid cells (ILC3)¹⁹. Considering that these Aire⁺ MHCII⁺
82 ILC3 (hereafter Aire⁺ ILC3s) also express the molecular machinery for antigen presentation and T
83 cell activation (MHCII, CD80, CD86, ICOSL)¹⁹, we investigated whether extrathymic expression
84 of *Aire* in this ILC3 subset may contribute to the adaptive immune response to *C. albicans*. Here
85 we show that Aire⁺ ILC3 cells sensed and internalized *C. albicans*, and effectively presented *C.*
86 *albicans* epitopes on their MHCII. Moreover, extrathymic (but not thymus-specific) ablation of
87 Aire impaired the expansion of the candida-specific T_H17 cell pool and resulted in overgrowth of
88 *C. albicans* at various mucosal surfaces.

89 RESULTS

90 **Aire⁺ ILC3s express receptors involved in *C. albicans* sensing**

91 To test whether peripheral expression of Aire in ILC3s was required for the induction or modulation
92 of an effective immune response to *C. albicans* infection, we determined whether ILC3s in general
93 and Aire⁺ ILC3s in particular expressed pattern recognition receptors (PRRs) for *C. albicans*. We
94 used *Rorc*-Cre⁺flox-STOP-flox-tdTomato reporter mice that were crossed with *Aire*-GFP⁺
95 transgenic reporter mice (hereafter *Rorc*^{Tomato} *Aire*^{GFP} mice), in which the tdTomato reporter is
96 expressed in all cells with a history of *Rorc* expression and the green fluorescent protein (GFP) is
97 expressed in cells with an active *Aire* locus. ILC3s isolated from the popliteal lymph node (pLN)
98 by flow cytometry-based sorting as lineage⁻(CD3, TCR-β, CD45RB, CD19, Gr1, F4/80, CD11b,
99 CD11c) *Rorc*-tdTomato⁺ cells were divided according to their MHCII and *Aire*-GFP expression
100 into MHCII⁻*Aire*-GFP⁻ conventional ILC3s (hereafter cILC3s), MHCII⁺*Aire*-GFP⁻ ILC3s
101 (hereafter MHCII⁺ ILC3s) and MHCII⁺*Aire*-GFP⁺ ILC3s (hereafter Aire⁺ ILC3s) (Fig. 1a). In
102 addition, to compare the molecular characteristics of these three ILC3 subsets with conventional
103 antigen presenting cells (APCs) that can sense *C. albicans*²⁰, we isolated CD11c⁺CD11b⁺ MHCII⁺
104 dendritic cells (DCs) from the *Rorc*^{Tomato} *Aire*^{GFP} mice. All sorted populations were analysed by
105 bulk RNA sequencing. Clustering analysis highlighted relatively large transcriptional similarity
106 between all cell subsets expressing MHCII (i.e. MHCII⁺ ILC3, Aire⁺ ILC3 and DC), and in
107 particular between the Aire⁺ ILC3s and MHCII⁺ ILC3s (Fig. 1b). All three ILC3 subsets were, as
108 expected, characterised by low expression of genes specific for hematopoietic stem cells (*Cd34*,
109 *Slamf1*), T cells (*Cd4*, *Cd8*, *Foxp3*); B cells (*Cd19*, *Cd79a*); granulocytes (*Ly6c1*, *Ly6g5b*, *Siglecf*);
110 macrophages and monocytes (*Itgam*, *Siglech*); dendritic cells (*Itgax*, *Csf1r*, *Cd207*) and had high
111 expression of genes associated with ILC3s (*Rorc*, *Il1r1*, *Il7r*, *Kit*, *Ccr6*) (Fig. 1c). Unlike cILC3s,
112 MHCII⁺ ILC3 and the Aire⁺ ILC3s had high expression of genes encoding MHCII (*H2-Aa*, *H2-*
113 *Ab1*) (Fig. 1d), while Aire⁺ ILC3s also had high expression of *Aire* and genes encoding

costimulatory molecules (*Cd80*, *Cd86*) at levels comparable to DCs (Fig. 1d). The Aire⁺ ILC3s also expressed transcripts for several key PRRs implicated in sensing *C. albicans*, such as *Tlr2*^{21, 22}, dectin-1 (*Clec7a*)^{23, 24} or galectin-3 (*Lgals3*)^{25, 26} (Fig. 1e) and signaling molecules downstream of these receptors (*Myd88*, *Syk*) (Fig. 1f). The protein expression of the *C. albicans*-sensing receptors including dectin-1, galectin-3 and Tlr2 on Aire⁺ ILC3s was confirmed by flow cytometry in steady-state conditions and was comparable to the expression on these receptors on DCs (Fig. 1g). These results collectively suggested that Aire⁺ ILC3s expressed genes implicated in antigen presentation, T cell activation¹⁹ and also *C. albicans* sensing.

***C. albicans* induces transcriptional changes in ILC3 subsets**

To test whether *C. albicans* could induce the activation of ILC3s in general, and Aire⁺ ILC3s in particular, we performed bulk RNA sequencing of Aire⁺ ILC3s, MHCII⁺ ILC3s and cILC3s sorted from pLN of *Rorc*^{Tomato} *Aire*^{GFP} mice that were intravenously injected at 1 day intervals for 3 days with heat-killed *Candida albicans* (HKCA) or PBS and analyzed 24 hours after the last injection. All three ILC3 subsets, and particularly the Aire⁺ ILC3s subset isolated from HKCA-challenged mice showed transcriptional changes compared to PBS-challenged controls (Fig. 2a-c). cILC3s from HKCA-challenged mice significantly upregulated 149 genes ($Fc \geq 2.0$, adjusted p-value ≤ 0.05) compared to PBS-treated controls (Fig. 2a), with genes encoding several PRR implicated in *C. albicans*-sensing (*Lgals3*, *Clec7a*, *Clec4d*, *Clec4e* and *Cd209b*) or molecules involved in antigen presentation (*H2-Aa*, *H2-Ab1*, *H2-Eb1* and *Cd74*), co-stimulation (*Cd86*) or induction of pro-inflammatory response (*Il1a*, *Il1b* and *Il18*) among the most upregulated (Fig. 2a, Extended Data Fig. 1a). This suggested that cILC3s may upregulate *Candida*-sensing receptors and/or MHCII molecules in response to the inflammatory conditions engendered by *C. albicans* stimulation. MHCII⁺ ILC3s from the HKCA-challenged mice significantly induced the expression of 641 genes, including *Aire*, which was the most significantly upregulated gene (p-value $\leq 1 \times 10^{-23}$; FC > 7)

compared to their PBS-their counterparts, and further upregulated the expression of *Clec7a* (dectin-1), *H2-Ab1* (MHCII) and *Cd86*, while downregulating the expression of several key ILC3-specific genes, such as *Il17a*, *Il17f* and *Il12rb1* (Fig. 2b, Extended data Fig. 1b). These observations suggested that the HKCA challenge potentiated the antigen presentation capacity of the MHCII⁺ ILC3 subset, while limiting their effector functions as IL-17-producing cells (Fig. 2b, Extended Data Fig. 1b). Moreover, fold-change/fold-change analysis comparing MHCII⁺ ILC3s from HKCA-stimulated vs. PBS-stimulated mice and Aire⁺ ILC3 vs. MHCII⁺ ILC3s from PBS-treated mice showed that MHCII⁺ ILC3s from HKCA-treated mice acquired a transcriptional signature similar to that of Aire⁺ ILC3s (Fig. 2d). This suggested that exposure of MHCII⁺ ILC3s to HKCA could likely initiate the acquisition of a transcriptional signature characteristic of Aire⁺ ILC3s (Fig. 2d, e, Extended Data Fig. 1d).

Finally, Aire⁺ ILC3s from HKCA-stimulated mice significantly upregulated 777 genes compared to PBS-treated mice, including cytokines or cytokine receptors (*Il6*, *Bmp2*, *Il7r*, *Il23r*, *Il2rb*), chemokines (*Ccl2*), *C. albicans*-sensing receptors (*Clec7a*), cell adhesion molecules (*Vcam1*, *Cadm1*), co-stimulatory molecules (*Cd86*) and enzymes involved in proinflammatory response (*Ptgs2*) (Fig 2c). Moreover, the HKCA challenge lead to a significant upregulation of *Il6*, which along with TGF- β , induces the polarization of naïve T cells to the T_H17 subset and their clonal expansion^{27, 28, 29} (Fig. 2c, Extended Data Fig. 1c). These results indicated that HKCA induced distinct transcriptional programs in the three ILC3 subsets analyzed, including the upregulation of genes involved in antigen presentation, co-stimulation and candida sensing in cILC3s and MHCII⁺ ILC3s, the upregulation of *Aire* in MHCII⁺ ILC3s and the upregulation of *Il6* in the Aire⁺ ILC3s, suggesting that Aire⁺ ILC3s could play a role in the induction or regulation of the adaptive immune response to *C. albicans*.

Aire⁺ ILC3s internalize *C. albicans* for antigen presentation

164 Next, we investigated whether Aire⁺ ILC3s could uptake *C. albicans* by endocytosis. To this end,
 165 we performed imaging flow cytometry (Imagestream) analysis of MACS-enriched lineage negative
 166 (Lin^{neg}: CD3⁻, TCR-β⁻, CD45RB⁻, CD19⁻, Gr1⁻, F4/80⁻, CD11b⁻, CD11c⁻) cell fraction or
 167 CD11c⁺DCs isolated from pLN and incubated ex-vivo with cell proliferation dye (CPD)-stained
 168 HKCA (HKCA-CPD). After 30 minutes of co-incubation, most Aire⁺ ILC3s were physically
 169 associated with HKCA-CPD (Fig. 3a), whether through cell-cell interactions or internalization of
 170 the HKCA-CPD into their cytoplasm. After 90 minutes of co-incubation, most Aire⁺ ILC3s had
 171 intracellular CPD signals (Fig. 3b), suggesting ingestion of HKCA-CPD. Vesicles containing
 172 internalized fungi fused with the lysosomes in both Aire⁺ ILC3s and DCs (Extended Data Fig. 2a),
 173 suggesting that Aire⁺ ILC3s had endocytic capacity for *C. albicans*. Moreover, while the capacity
 174 of Aire⁺ ILC3s to endocytose HKCA-CPD was comparable to CD11c⁺ or CD11b⁺ mononuclear
 175 phagocytes (MNPs) (Extended Data Fig. 2b), the endocytic capacity of both MHCII⁺ ILC3s and
 176 cILC3s was substantially lower than that of Aire⁺ ILC3s (Extended Data Fig. 2b). Moreover,
 177 similarly to DCs, the endocytic capacity of Aire⁺ ILC3s cells was partially dependent on the
 178 expression of dectin-1 and galectin-3 and was reduced at 4°C (Extended Data Figure 2c, d).

179 To assess the capacity of Aire⁺ ILC3s to present candida-derived antigens under *in vitro* conditions,
 180 we FACS-sorted pLN-resident Aire⁺ ILC3s and other types of APCs (B cells, Ly6C⁺ MNPs,
 181 CD11b⁺ MNPs, CD11c⁺ MNPs) from Balb/c wild-type mice using a gating strategy described in
 182 Extended Data Fig. 2e), stimulated them with HKCA or transgenic HKCA expressing OVA
 183 (HKCA-OVA) and incubated them for 17 hours with an NFAT-GFP DO11.10 TCR reporter cell
 184 line⁴, which turn on GFP expression in response to TCR stimulation by OVA³²³⁻³³⁹ peptide
 185 presented in the context MHCII molecules. Based on this *in vitro* assay, CD11b⁺ MNPs were the
 186 most efficient APCs (Fig. 3c), while CD19⁺ B cells and Ly6C⁺ MNPs showed negligible antigen
 187 presentation capacity (Fig 3c). The Aire⁺ ILC3s showed substantial capacity to present HKCA-

188 derived antigens, comparable to that of CD11c⁺ MNPs and ~5-fold lower than that of CD11b⁺
189 MNPs (Fig. 3c; Extended Data Fig. 2f).

190 To assess the capacity of Aire⁺ ILC3s to present candida-derived antigens under more physiological
191 conditions, we sorted Aire⁺ ILC3s and other types of APCs (B cells, Ly6C⁺ MNPs, CD11b⁺ MNPs,
192 CD11c⁺ MNPs) from the pLNs of Balb/c wild type mice injected with either HKCA-OVA or
193 HKCA at 12, 24 or 72 hours before sorting (Extended Data Fig. 2g). The sorted cells were then co-
194 incubated with the NFAT-GFP DO11.10 TCR reporter cells line for 17 hours and their antigen
195 presentation capacity was determined by the frequency of cells expressing the NFAT-GFP reporter.
196 CD11b⁺ MNPs isolated 12 hours after the HKCA challenge showed the highest antigen presentation
197 capacity, as measured by the frequency of NFAT-GFP⁺ cells (~1.7%) (Fig. 3d, Extended Data Fig.
198 2h). Their capacity to induce the NFAT-GFP signal declined at 24 hours (Fig. 3e, Extended Data
199 Fig. 3d) and largely diminished at 72 hours after the HKCA challenge (Fig. 3f, Extended Data Fig.
200 2h). Both, Aire⁺ ILC3s and CD11c⁺ MNPs induced the highest frequency of NFAT-GFP⁺ cells
201 (1.2% and 0.7 % respectively) at 72 hours after the HKCA challenge (Fig. 3f, Extended Data Fig.
202 2h). These data suggested that while CD11b⁺ MNPs dominated the early antigen-presentation
203 phase, Aire⁺ ILC3s were more efficient at presenting candida-derived antigens at later timepoints.

204 To examine the capacity of Aire⁺ ILC3s to present *C. albicans*-derived antigens to T cells in the
205 pLNs, we performed *ex vivo* two-photon imaging in Aire-GFP reporter mice that were adoptively
206 transferred with OT-II T cells bearing OVA-specific TCR and endogenously expressing tdTomato
207 fluorescence protein (OT-II^{tdTomato}). The mice were intravenously stimulated either with HKCA-
208 OVA or HKCA as control, and two-photon excitation microscopy on explanted pLNs was used to
209 visualize the interactions between Aire-GFP⁺ cells and OVA-specific OT-II^{tdTomato} T cells (Fig. 3g).
210 While we did not observe any physical interaction between Aire-GFP⁺ cells and OT-II^{tdTomato} T cells
211 in pLNs isolated from mice stimulated with HKCA, we observed numerous such interactions in
212 pLNs isolated from mice stimulated by HKCA-OVA (Fig. 3g). These observations suggested that

Aire⁺ ILC3s might present candida-derived antigens to T cells and that they could exert this function at later timepoints compared to conventional APCs.

Aire⁺ ILC3s are required for induction of candida-specific T_H17

To determine whether Aire⁺ ILC3s, and, in particular, the expression of *Aire* in these cells regulated the adaptive immune response to *C. albicans*, we aimed to conditionally inactivate Aire in Aire⁺ ILC3s. To this end, we generated *Rorc*-Cre⁺*Aire*^{fl/fl} (hereafter ILC3^{ΔAire})^{30, 31}, in which Aire is ablated in all cells that either actively express *Rorc* or have *Rorc* expression history. Because the expression of Aire in the pLNs of wild-type mice was restricted to Lin^{neg}Roryt⁺MHCII⁺ cells¹⁹ (Extended Data Fig. 3a, b), this strategy allowed us to specifically inactivate Aire expression in Aire⁺ ILC3s. As controls, we generated *Foxn1*-Cre *Aire*^{fl/fl} mice (hereafter TEC^{ΔAire}), in which Aire is deleted in thymic epithelial cells (TEC). Using flow cytometry, we could not detect any Aire protein expression in samples prepared from the pLN of ILC3^{ΔAire} mice, while Aire protein was detected in the ILC3^{ΔAire} thymus samples (Fig. 4a). Conversely, Aire protein was detected in the pLNs, but not the thymus, of TEC^{ΔAire} mice (Fig. 4a). We next intravenously transferred naïve OT-II T cells from CD45.1 expressing GFP fluorescent protein under the *Rorc*-promoter (OT-II-*Rorc*-GFP) equally mixed with control polyclonal T cells from CD45.1/CD45.2 wild-type mice into CD45.2 positive wild-type or ILC3^{ΔAire} mice, followed by stimulation of recipient mice with HKCA-OVA or HKCA as control in consecutive 2 days intervals and analyzed 2 or 14 days after the first injection. While no significant differences in OT-II-*Rorc*-GFP T cell cellularity and/or proliferation were observed at day 2 post-transfer between the HKCA-OVA or HKCA-stimulated wild-type vs. ILC3^{ΔAire} mice (Extended Data Fig. 3 c,d), the OT-II-*Rorc*-GFP T cells transferred in the HKCA-OVA-stimulated wild-type mice showed a ~2.5 fold proliferative expansion at day 14 post-transfer compared to the HKCA-OVA-stimulated ILC3^{ΔAire} mice (Fig. 4b, c). The frequency

of CD45.1⁺ OT-II T cells in the HKCA-OVA-treated ILC3^{ΔAire} mice was decreased by > 8-fold compared to HKCA-OVA-treated wild-type controls (Fig. 4b, c). Moreover, approximately 10% of the CD45.1⁺ OT-II T cells transferred in the HKCA-OVA-stimulated wild-type mice differentiated into *Rorc*-GFP⁺ T_H17 cells (Fig. 4d). In contrast, the frequency (Fig. 4d) and number (Fig. 4e) of CD45.1⁺ *Rorc*-GFP⁺ OT-II T_H17 cells in HKCA-OVA-treated ILC3^{ΔAire} was reduced by ~20 fold and ~100-fold, respectively, compared to HKCA-OVA-treated wild-type controls at day 14 post-transfer, suggesting that *Aire* expression in ILC3s was required for the induction of effector T_H17 cells in response to *C. albicans* stimulation.

Next, we performed MHCII tetramer staining for *C. albicans*-specific epitopes derived from the agglutinin-like protein 1 (Als1). Specifically, pooled spleen or pLN-resident CD4⁺ T cells isolated from ILC3^{ΔAire}, TEC^{ΔAire} or their wild-type littermates that had been stimulated with HKCA for two weeks prior to isolation were stained with Als1-specific tetramers (Als1-Tet) and analyzed by flow cytometry. We observed a significant reduction in the number of Als1-Tet⁺CD44⁺CD4⁺ activated T cells isolated from the spleen and pLNs of ILC3^{ΔAire} mice compared to wild-type or TEC^{ΔAire} mice (Fig 4f, g), suggesting that extrathymic, but not thymic expression of *Aire* was critical for the induction of candida-specific T cells.

To investigate whether a similar defect of T cell response to candida was found in APS-1 patients, we stimulated the peripheral blood mononuclear cell (PBMC) fraction from APS-1 patients or healthy individuals with HKCA and monitored T cell proliferation four days later. We observed a significant decrease (~3-fold) in both the frequency of HKCA-induced RorγT⁺ T_H17 cells (Fig. 4h, i), as well as in the amount of IL-17A released in supernatants from PBMCs isolated from APS-1 vs. healthy controls (Fig. 4j). Collectively, these data suggest that expression of *Aire* in ILC3s was required for the expansion of candida-specific CD4⁺ RorγT⁺ T cell clones.

Extrathymic Aire is critical for effective response to *C. albicans*

Next, we sought to determine whether loss of Aire expression in ILC3s could impair the clearance of live *C. albicans* *in vivo*. Because *C. albicans* is generally completely absent in mice housed under specific pathogen free (SPF) conditions³², implying that SPF mice would have limited adaptive immune response to this pathogen, we pretreated wild-type and ILC3^{ΔAire} mice for 3 weeks with intravenous (*i.v.*) injections of HKCA, before *i.v.* administration of live *C. albicans*. ILC3^{ΔAire} mice were significantly more susceptible to *C. albicans* challenge, with only ~10% survival at 14 days post-challenge, compared to wild-type littermates, which had a ~50% survival rate at this time point (Fig. 5a). Moreover, the ILC3^{ΔAire} mice showed a significantly higher burden of *C. albicans* in their kidneys in comparison to wild-type littermate controls (Fig. 5b, c and Extended Data Fig. 3g, h). Similarly, *Aire*^{-/-} mice on either B6 or NOD genetic backgrounds had significantly lower survival rate following *i.v.* injection of live *C. albicans* (with 20% and 0% survival respectively) compared to their *Aire*^{+/+} littermates (with 60% and 45% survival respectively) (Extended Data Fig. 3e-f). While the *Aire*^{-/-} mice on the B6 background had significantly poorer survival rate than their wild-type littermates, they did not develop detectable levels of IL-17- and/or IL-22-specific autoantibodies (Extended Data Fig. 3i-j), further suggesting that the impaired anti-candida response was primarily T cell dependent.

Next, we assessed the adaptive immune response to live *C. albicans* in a mucosal model of infection. We used a modified version of an existing protocol³³, which is based on the oral administration of live *C. albicans* to mice in 3 consecutive times with 1 day intervals, resulting in a long-lasting colonization of their gastro-intestinal tract. First, we assessed whether oral candida colonization of wild-type mice resulted in the expansion of candida-specific T cells in the secondary lymphoid organs (SLO) (Fig. 6a, b; Extended Data Fig. 4 a, b). Flow cytometry indicated that while wild-type mice not treated with oral *C. albicans* harbored relatively low numbers of Als1-Tet⁺ T cells (3-5 naïve CD44⁻ T cells/SLO in each mouse analyzed), the number of Als1-Tet⁺ T

286 cells increased by ~50-100-fold at day 14 post *C. albicans* colonization (Fig. 6a, b), and virtually
287 all of them had an activated memory phenotype, as evidenced by high expression of CD44 (Fig.
288 6a). In contrast, *C. albicans* colonization of ILC3^{ΔAire} mice (Fig. 6c, d), Aire^{-/-} mice (Extended Data
289 Fig. 4c-e) or bone-marrow chimeric mice in which Aire deficiency occurred in the hematopoietic,
290 but not in the stromal compartment (Extended Data Fig. 4f-h), resulted in significantly decreased
291 numbers of Als1-Tet⁺ T cells in the SLO than did *C. albicans* colonization of their corresponding
292 wild-type littermate controls. Moreover, low numbers of Als1-Tet⁺ T cells were also observed in
293 CD90.2 Rag1^{-/-} mice that were adoptively transferred with CD90.1⁺ T cells and B cells and treated
294 with a CD90.2-specific antibody to deplete the endogenous CD90.2 lymphoid compartment, thus
295 rendering them ILC-deficient³⁴ compared to isotype control-treated mice (Extended Data Fig. 4j-
296 k).

297 We next investigated the presence of candida-specific T cells at different mucosal sites of the
298 gastrointestinal tract at day 1 or day 14 post *C. albicans* administration. While Als1-Tet⁺ T cells
299 could not be detected in the oral cavity, esophagus or small intestine mucosa from wild-type, Aire^{-/-}
300 or ILC3^{ΔAire} mice 24 hours post *C. albicans*-challenge (Extended Data Fig. 5), they were present
301 in these locations in wild-type mice at day 14 post-challenge (Fig. 6g, h; Extended Data Fig. 5). In
302 contrast, ILC3^{ΔAire} or Aire^{-/-} mice had markedly reduced numbers of Als1-Tet⁺ T cells at these sites
303 along the gastrointestinal tract, in particular in the lamina propria, at day 14 post-challenge
304 compared to their corresponding wild-type controls (Fig. 6g, h; Extended Data Fig. 5). In addition,
305 the number of the bulk Rorγt⁺ T_H17 population in pLN and mLN isolated was higher in wild-type
306 mice compared to ILC3^{ΔAire} mice at day 14 post *C. albicans* colonization (Extended Data Fig. 6).
307 In contrast the number of Rorγt⁺ T_H17 cells within lamina propria were similar in wild-type mice
308 and ILC3^{ΔAire} mice at this time point (Fig. 6i,k), suggesting that while ILC3-specific Aire deficiency
309 impaired the expansion of candida-specific T_H17 cells in the lymphoid organs and lamina propria,
310 the effect on the general T_H17 population was smaller and more variable. In line with the decreased

number of candida-specific T cells at mucosal surfaces, the *Aire*^{-/-} and ILC3^{ΔAire} mice had a significantly higher burden of *C. albicans* in their gastrointestinal mucosal sites compared to their wild-type littermates at day 14 post-challenge (Fig. 6k, l; Extended Data Fig. 7).

Finally, we also utilized a more conventional model for oropharyngeal candidiasis (OPC)³⁵, in which the oral mucosal tissue in mice was exposed to live *C. albicans* for 90 minutes. In this setting, we pre-treated wild-type and ILC3^{ΔAire} mice with *i.v.* injection of HKCA every 2 days for 14 days prior to the OPC challenge with live *C. albicans*, and the oral mucosa was analyzed at day 5 after the OPC challenge (Extended Data Fig. 8a). At this timepoint, we observed significantly less Als1-Tet⁺ T cells (Extended data Fig. 8b,c) and a higher burden *C. albicans* (Fig. 6m) in the oral mucosa of ILC3^{ΔAire} compared to wild-type mice (Extended Data Fig. 7b,c). Collectively, these data demonstrated that Aire expression in Aire⁺ ILC3s was required for the induction of adaptive immune responses to *C. albicans* at the mucosal surfaces.

Aire⁺ ILC3 induce survival of candida-specific T_H17 clones

To explore how expression of Aire in Aire⁺ ILC3s promoted the expansion of *C. albicans* specific T cells, we assessed the impact of Aire deficiency on the gene expression profiles of Aire⁺ ILC3s and candida-specific T cells in response to *C. albicans* challenge. For this purpose, we crossed *Aire*^{-/-} mice with *Aire*-GFP reporter mice, to generate *Aire*-GFP-*Aire*^{-/-} mice. Aire⁺ ILC3s sorted (based on *Aire*-GFP expression) from *Aire*-GFP-*Aire*^{-/-} or *Aire*-GFP-*Aire*^{+/+} littermates that had received HKCA or PBS *i.v.* every day for 3 days (Extended Data Fig. 9) were analyzed by bulk RNAseq analysis on day 4. Analysis of these transcriptomes indicated that Aire regulated the expression of hundreds of genes, which strongly overlapped with the genes upregulated in response to HKCA (Fig. 7a, b). Specifically, the Aire⁺ ILC3s isolated from HKCA-stimulated *Aire*-GFP-*Aire*^{-/-} mice had impaired induction of genes encoding cytokines (*Il6*, *Il18*, *Bmp2*), *C. albicans*-sensing

335 receptors (*Clec7a*), cell adhesion molecules (*Vcam1*, *Cadm1*), co-stimulatory molecules (*Cd86*)
 336 and enzymes involved in proinflammatory response (*Ptgs2*) compared to their HKCA-stimulated
 337 *Aire*-GFP-*Aire*^{+/+} counterparts (Fig 7a, b). These data suggested that Aire regulated the expression
 338 of several key molecules that may be critical for T_H17 differentiation (*Il6*), T cell clonal expansion
 339 (*Cd80/Cd86*; *Vcam1*) and pro-inflammatory signaling (*Il18*, *Ptgs2*).

340 To investigate how Aire deficiency impacted the transcriptional program of *C. albicans*-specific T
 341 cells, we adoptively transferred *Rorc*-GFP⁺ OT-II T cells into wild-type or ILC3^{ΔAire} mice that were
 342 stimulated with HKCA-OVA or HKCA every second day. *Rorc*-GFP⁺ OT-II T cells were then
 343 isolated from pLN on day 7 post-transfer and analyzed by bulk RNA sequencing (Extended Data
 344 Fig. 10a). At this time point, the frequencies of *Rorc*-GFP⁺ OT-II T cells in ILC3^{ΔAire} mice were
 345 decreased by ~3-fold compared to wild-type littermates (Extended Data Fig. 10b). We observed
 346 only mild increase in the frequency of CPD⁺ proliferating *Rorc*-GFP⁺ OT-II T cells in wild-type vs
 347 ILC3^{ΔAire} mice (Extended Data Fig. 10b), suggesting that Aire was not involved in the regulation
 348 of *Rorc*-GFP⁺ T cell priming.

349 The transcriptional analysis indicated that the *Rorc*-GFP⁺ OT-II T cells had substantially different
 350 transcriptomes compared to the non-proliferating CPD⁺ OT-II T cells. Specifically, the *Rorc*-GFP⁺
 351 OT-II T cells isolated from wild-type mice upregulated 551 genes, including *Rorc*, *Cd44*,
 352 chemokine receptor *Ccr5* and proliferation marker *Mki67* and downregulated 220 genes, including
 353 *Sell* and *Cd69*, compared to the non-proliferating CPD⁺ OT-II T cells from wild-type mice (Fig. 7C
 354 and Extended Data Fig. 10b), highlighting their activated/memory phenotype and readiness to exit
 355 the lymph node and move to the effector site. We detected more than a thousand differentially
 356 expressed genes between the *Rorc*-GFP⁺ OT-II T cells derived from the wild-type compared to the
 357 ILC3^{ΔAire} mice (Fig 7c, and Extended Data Fig. 10b). Specifically, *Rorc*-GFP⁺ OT-II T cells isolated
 358 from ILC3^{ΔAire} mice had significantly reduced expression of anti-apoptotic factors such as survivin
 359 (*Birc5*) or *Bcl2l12*³⁶ and a less activated/memory phenotype, as suggested by the decreased

expression of the chemokine receptor *Cxcr3*, *Il2rb* (encoding the IL-2 receptor beta subunit), *Igf2r*³⁷, *Il12rb1* (the key subunit of IL-23 receptor; Fig 7d, e) and *Cd28*, encoding the CD80/86 receptor essential for T cell co-stimulation (Fig. 7e). The GO annotation of cell processes indicated that the differentially regulated genes were highly enriched for factors involved in the regulation of cell cycle and/or mitosis (Fig. 7f). Collectively, these data suggested that Aire controlled the expression of genes in Aire⁺ ILC3s (e.g. *Il6*, *Cd86*, *Ptgs2*) that were critical for the subsequent induction of a pro-survival transcriptional program in T_H17 cells (Extended Data Fig. 10d, e).

DISCUSSION

Here we show that extrathymic expression of Aire in Aire⁺ ILC3s was required for the expansion of candida-specific CD4⁺ T cells, in particular T_H17 clones, in response to *C. albicans* infection and for consequently limiting the pathogenicity of this opportunistic pathogen at mucosal tissues. We found that Aire⁺ ILC3s expressed receptors implicated in *C. albicans* detection (e.g. dectin-1, galectin-3) at levels comparable to DCs and effectively endocytosed *C. albicans*. Moreover, upon *C. albicans* uptake, Aire⁺ ILC3s presented candida-derived antigens to CD4⁺ T cells through MHCII. Therefore, our study suggests that effective response to *C. albicans* infection involves division of labor between different types of phagocytes and APCs, with Aire⁺ ILC3s playing a non-redundant role in promoting the survival and subsequent expansion of candida-specific T cell clones in the LN.

While ILCs are generally viewed as the innate analogs of T cells, a growing body of evidence suggests that some ILC subsets are, similarly to Aire⁺ ILC3, equipped with potent endocytic and/or antigen presentation capacity^{38, 39, 40, 41, 42, 43}. For instance, spleen-derived NCR⁺CCR6⁺MHCII⁺ ILC3s, were reported to internalize latex beads and present model protein antigen to CD4⁺ T cells *in vitro*⁴³. Similarly, MHCII⁺ ILC2 can endocytose and present OVA protein and induce antigen-

specific T cell proliferation⁴², while intestinal MHCII⁺ ILC3s were reported to regulate T cell responses to bacterial antigens in an antigen dependent manner^{38, 40, 41}, arguing that some ILC3 subsets may act as potent APCs, with the capacity to modulate antigen-specific T cell responses in different contexts and in different anatomical niches³⁸. Moreover, our data also suggested that LN-resident MHCII⁻ ILC3s could upregulate the expression of MHCII and CD86 coding genes in response to *C. albicans* challenge. This is in line with reports showing that the pro-inflammatory cytokine IL-1 β promotes the expression of MHCII and costimulatory molecules on spleen-, but not gut-derived MHCII⁻ ILC3s⁴³.

Moreover, our data indicated that the impaired expansion of candida-specific CD4⁺ T cells in SLO of ILC3 ^{Δ Aire} mice was associated with their decreased accumulation at different mucosal sites, including the oral cavity, esophagus and intestine, and with increased burden of *C. albicans* at these mucosal tissues. It is likely that the impaired surveillance of the mucosal tissues due to a loss of candida-specific CD4 T cells resulted in reduced ability to control the fungal burden at the mucosal surfaces and loss of barrier integrity. In Aire-deficient patients, in which both the extrathymic and the thymic expression of Aire are defective, additional mechanisms (e.g. autoantibodies against IL-17, IL-22^{17, 18, 44}, defensins⁴⁵ and mucins⁴⁶ or loss of Paneth cells⁴⁵) may further impair the integrity of mucocutaneous surfaces and thereby enhance the invasiveness of *C. albicans*. Therefore, the increased susceptibility to *C. albicans* in Aire-deficiency may combine aspects of the role of Aire in central tolerance with its role in shaping the *C. albicans*-specific T_H17 response in the periphery.

Although our data are in line with the interpretation that the increased susceptibility to candida infection in both humans and mice is due to defects in the T_H17 response^{12, 14, 15, 47, 48}, it was also suggested that in the oral mucosa, Aire-deficient mice and humans have intact T_H17 responses to *C. albicans* and that these phenotypes are due to overproduction of interferon- γ (IFN- γ) in CD4⁺ and CD8⁺ T cells at the epithelial barriers⁴⁹. In this specific study, however, the T_H17 response was measured only 24 hours post *C. albicans* challenge⁴⁹, which might be too early a

timepoint to assess an adaptive immune response, because *C. albicans* is virtually absent in mice housed under SPF conditions^{32, 33}. Indeed, we found that the induction of candida-specific T cells in SPF-housed mice peaked only two weeks post *C. albicans* colonization. In addition, the report assessed bulk T_H17 cell responses⁴⁹, and not candida-specific T cell clones as it was done in this study.

The molecular features of Aire⁺ ILC3s described here seem to largely overlap with a subset of Lin^{neg}Aire⁺Rorc⁺MHCII⁺ Janus cells that was recently identified using single-cell RNA profiling of mouse LN⁵⁰, suggesting they might represent the same cell population. Although the study suggested that the Lin^{neg}Aire⁺Rorc⁺MHCII⁺ Janus cells are a subset of tolerogenic DCs⁵⁰, they lacked expression of key DC canonical markers such as *Cd11c*, *Cd11b*, *Dec205*, *Clec9a* or *Cd4/Cd8*⁵⁰, as well as of other key myeloid or lymphoid markers. Moreover, similarly to Aire⁺ ILC3s, the Janus cells highly expressed ILC3 markers, including *Rorc*, *Il1r1*, *c-Kit*, *il7r*, *Id2*, *Ccr6*, *Ccr7*, *Il18r1*, as well as genes linked to antigen presentation and co-stimulation. Therefore, although both Aire⁺ ILC3 and Janus cells lacked the expression of key ILC3 effector molecules such as *Il17a*, *Il17f* or *Il22*, they bore molecular features more characteristic of MHCII⁺ innate lymphoid cells, rather than of myeloid APCs. This notion is also supported by a recent study showing that extrathymic Lin^{neg}Aire⁺Rorc⁺MHCII⁺ cells have an interconverting potential with ILC3s in a fate mapping analysis based on *Aire*-Cre reporter mice⁵¹. Irrespectively of nomenclature, our study provides experimental evidence that the expression of Aire in LN-resident Lin^{neg}Aire⁺Rorc⁺MHCII⁺ cells has a critical and a non-redundant role in the induction of candida-specific T cells and the control of *C. albicans* colonization at mucosal tissues.

Collectively, our data not only help shedding more light on the mechanisms underlying chronic mucocutaneous candidiasis in Aire-deficient individuals, but also help identifying an additional

433 functional role for Aire, beyond its well-established role in central tolerance induction in the
434 thymus.

AUTHORS CONTRIBUTION

JA and JD conceived the project, designed the experiments and wrote the manuscript; JD performed the experiments and analyzed the data; JA supervised the study; AB, YG, OB-N, NK, YG, TG, IZ, HB, KK, EV, BEO and ESH assisted at different aspects of the study, including data or sample acquisition and analysis. DF contributed by the essential reagent. LSB and ZS performed the two-photon microscopy and analyzed the data.

CFI statement : The authors declare that they have no conflict of interest

FIGURE LEGENDS

Figure 1| *Aire*⁺ ILC3s express *C. albicans* sensing receptors.

a) FACS sorting strategy of cILC3s, MHCII⁺ ILC3s and *Aire*⁺ ILC3s subsets isolated from the popliteal lymph nodes of *Rorc*^{tdTomato} *Aire*^{GFP} reporter mice. Representative plots are shown. **b)** Heatmap of Pearson correlation according to gene expression values between individual samples as in a). **c-f)** RNA-seq based heatmap of expression of lineage specific genes (**c**), genes associated with MHCII-presentation or co-stimulation (**d**), genes encoding receptors implicated in sensing and/or phagocytosis of *C. albicans* (**e**) and genes encoding signaling molecules downstream of *C. albicans* sensing receptors (**f**) in cILC3s, MHCII⁺ ILC3s, *Aire*⁺ ILC3s and MHCII⁺ CD11c⁺ DCs isolated from popliteal lymph nodes of *Rorc*^{tdTomato} *Aire*^{GFP} at steady-state. **g)** Flow cytometry of Rorγt⁺ cILC3s, Rorγt⁺ MHCII⁺ ILC3s, Rorγt⁺ MHCII⁺ *Aire*⁺ ILC3s and MHCII⁺ CD11c⁺ DCs isolated from popliteal lymph nodes of wild-type animals under steady-state conditions. Grey filled histogram indicates staining in control dectin-1 or galectin-3-deficient mice or isotype control for CD80, CD86, TLR2. Representative figure, n≥3.

Figure 2| *C. albicans* induces transcriptional changes in ILC3 subsets

a-c) Volcano plots of bulk RNA-seq analyses showing differential gene expression in non-stimulated vs. HKCA stimulated cILC3 (**a**), MHCII⁺ ILC3 (**b**) and *Aire*⁺ ILC3 (**c**) subpopulations isolated from the popliteal lymph nodes of *Rorc*^{tdTomato} *Aire*^{GFP} mice *i.v.* injected by HKCA or PBS for three consecutive days, using gating strategy as in Fig. 1a. Dashed lines indicate the cutoff for fold-change (Fc)=2.0 and p-value=0.05. Wald test was used to calculate the p-value. Based on their function, the selected genes were highlighted in blue (antigen presentation, co-stimulation), red (cytokine and chemokine signaling), green (candida sensing receptors), purple (*Aire*); **d)** Fold change:fold change (Fc:Fc) graph of RNA-seq data showing differential gene expression in *Aire*⁺ ILC3s in contrast to stimulated or non-stimulated MHCII⁺ ILC3s. Comparison of fold-change of *Aire*⁺ ILC3s vs. MHCII⁺ ILC3s (x-axis) and non-stimulated vs. HKCA stimulated MHCII⁺ ILC3s (y-axis) isolated by FACS using a gating strategy as in Fig. 1a. Dashed lines indicate the Fc=2.0 cutoff. **e)** RNA-seq-based heatmap showing the level of expression of selected effector genes in ILC3s, MHCII⁺ ILC3s and *Aire*⁺ ILC3s with or without HKCA stimulation. Data are plotted as the z-score calculated for particular row. Data are derived from three independent biological replicates for each population (a-e).

491

492 **Figure 3| Aire⁺ ILC3s internalize *C. albicans* for antigen presentation**

493 **a-b)** Imaging flow cytometry showing the physical interaction between HKCA and Aire⁺ ILC3s
494 isolated from popliteal lymph nodes of wild-type mice and incubated ex-vivo with CPD-stained
495 HKCA for 30 (a) or 90 minutes (b). Samples were stained for Aire and DAPI (a-b) and MHCII
496 (b). Shown are representative images of one out of five independent experiments. Scale bar: 8µm.
497 **c-f)** *In vitro* reporter assay measuring the capacity of B cells, Ly6C⁺ MNPs, CD11b⁺ MNPs, CD11c⁺
498 MNPs and Aire⁺ ILC3s to endocytose HKCA transgenically expressing OVA (HKCA-OVA) either
499 *in vitro* (c) or *in vivo* (d-f) and subsequently to present HKCA-derived OVA antigens on their
500 MHCII molecules to DO11.10-TCR NFAT-GFP reporter cell line that was co-incubated with the
501 sorted populations for 17 hours. The corresponding APC populations were FACS-sorted according
502 to gating strategy shown in Extended Data Fig. 3a, b. Antigen presentation capacity was measured
503 as a frequency of NFAT-GFP⁺ reporters in the specific sample. Representative data set out of three
504 independent experiments are shown (n=5 for each experiment), mean ± SD depicted. (d-f) Dot plot
505 of B cells, Ly6C⁺ MNPs, CD11b⁺ MNPs, CD11c⁺ MNPs and Aire⁺ ILC3s depicting APC capacity
506 at 12 hours (d), 24 hours (e) or 72 hours (f) after HKCA-OVA i.v. injection of HKCA-OVA into
507 wild-type mice; g) Two-photon microscopy of explanted popliteal lymph nodes showing interaction
508 between Aire-GFP⁺ cells and candida-specific T cells from Aire-GFP reporter mice adoptively
509 transferred with OT-II^{tdTomato} T cells stimulated by either HKCA or HKCA-OVA. Representative
510 figures from two experiments are shown.

511

512 **Figure 4| Aire⁺ ILC3s are essential for the generation of *C. albicans*-specific T_H17 response**

513 **a)** Flow cytometry analysis showing disruption of Aire-expression *Rorc*-Cre⁻Aire^{fl/fl} (WT) and
514 *Rorc*-Cre⁺Aire^{fl/fl} (ILC3^{ΔAire}) mice. Shown are representative FACS plots (n≥6) of intracellular
515 Aire-staining of thymic stroma (upper panel) or lineage negative cells from pLNs (lower panel); **b-**
516 **e)** Flow cytometric analysis of OT-II T cell proliferation and differentiation in WT or ILC3^{ΔAire}
517 mice transferred with naïve OT-II and control CD4⁺ T cells in 1:1 ratio and subsequently injected
518 with HKCA or HKCA-OVA every second day for 2 weeks showing representative flow cytometry
519 dot plot show the frequencies of transferred CD45.1⁺ OT-II T cell vs. CD45.1/CD45.2 double
520 positive control T cell populations on day 14 post-transfer (b), the corresponding statistical analysis
521 showing ratios (mean ± SD, two-tailed Student's t-test) of OT-II vs. control T cells (n=5 per group)
522 (c), the frequencies of OT-II *Rorc*-GFP⁺ cells (d) and the corresponding statistical analysis of the

experiment showing the total counts (mean \pm SD, two-tailed Student's t-test) of HKCA-induced OT-II *Rorc*-GFP⁺ cells (**e**); **f-g**, Flow cytometric analysis assessing counts of Als1-tetramer positive CD4 T cells in WT, ILC3 ^{Δ Aire} and TEC ^{Δ Aire} mice that were injected intravenously with HKCA every second day for two weeks showing representative FACS plot (**f**) and the corresponding statistical analysis depicting the total counts (mean \pm SD, two-tailed Student's t-test) in all mice (n=5) (**g**); **h-i**) Flow cytometric analysis assessing the proliferation of human Ror γ T⁺ T_H17 cells in PBMCs isolated from APS-1 patients or healthy controls showing representative dot plots of the frequency of proliferating Ror γ T⁺ T_H17 cells measured by CPD dilution (**h**) and the corresponding statistical analysis of the experiment depicting average frequency (mean \pm SD, two-tailed Student's t-test, n=10 per group) (**i**); **j**) ELISA assessing amounts of IL-17A in the PBMC supernatants from proliferation assay described in (**h**). Data are shown as mean of IL-17A concentration \pm SD, n=10 for each group, two-tailed Student's t-test. P-value indicators: *** = p-value < 0.0001, ** = p-value < 0.001, * = p-value < 0.05, ns = not significant.

Figure 5| Mice lacking extrathymic expression of Aire have reduced survival after systemic challenge with live *C. albicans*

a) Survival curves of WT (Cre⁻ Aire^{fl/fl}) and ILC3 ^{Δ Aire} (*Rorc*-Cre⁺ Aire^{fl/fl}) mice (n \geq 10 per genotype group) injected *i.v.* with HKCA every two days for three weeks prior the infection by live *C. albicans*. Long-rank (Mantel-Cox) test was used to calculate the p-value: 0.0414; **b)** Quantitative PCR analysis of *C. albicans*-specific DNA in the kidney from WT and ILC3 ^{Δ Aire} mice (n=6) infected with *C. albicans* as in **a** (mean \pm SD, two-tailed Student's t-test); **c)** Colony forming units (CFU)-based assay determining the overgrowth of *C. albicans* in kidneys of mice described in (**a**), (n=6, mean \pm SD, two-tailed Student's t-test). P-value indicators: *** = p-value < 0.0001, ** = p-value < 0.001, * = p-value < 0.05, ns = not significant.

Figure 6| Extrathymic expression of Aire is critical for an effective T_H17 response to *C. albicans* at mucosal sites

a-b) Flow cytometry analysis assessing frequencies of *C. albicans*-specific Als1-Tet⁺, CD4⁺ T cells in pLNs of WT mice orally colonized by *C. albicans* and analyzed at different time points post colonization. Representative FACS plot showing counts of Als1-tet⁺, *C. albicans*-specific CD4⁺ T cells (highlighted in red rectangles in the upper panel and red dots in the lower panel showing T cell activation markers CD44 vs CD69) (**a**) with a corresponding statistical analysis of the same

experiment showing the total counts (mean +SD, two-tailed Student's t-test **(b)**; **c-j**) Flow cytometry analysis assessing frequencies of *C. albicans*-specific Als1-Tet⁺, CD4⁺ T cells in pLNs **(c-f)** or intestinal lamina propria **(g-j)** of WT vs. ILC3^{ΔAire} mice orally colonized by *C. albicans* and analyzed two weeks post colonization. Representative FACS dot plots showing counts of tetramer positive CD4 T cells **(c, g)** and RorγT⁺ CD4 T cells **(e, i)** are highlighted in black and red rectangles respectively. Statistical analyses showing the total counts (mean +SD, two-tailed Student's t-test, n=6 per group) corresponding to data shown in **(c, e, g, i)** are shown in **(d, f, h, j)** respectively. Representative experiment out of three independent biological replicates is shown. **(k)** Quantitative PCR analysis assessing the presence of *C. albicans*-specific DNA in the ileal part of small intestine from WT and ILC3^{ΔAire} mice (mean +SD, two-tailed Student's t-test, n=6 per group). **(l)** Colony forming units (CFU)-based assay determining the overgrowth of *C. albicans* in small intestinal tissues 14 days after oral colonization (mean +SD, two-tailed Student's t-test, n=6 per group). **(m)** CFU-based assay determining the overgrowth of *C. albicans* in oral mucosa 6 days after OPC challenge (mean +SD, two-tailed Student's t-test, n=6 per group). P-value indicators: *** = p-value < 0.0001, ** = p-value < 0.001, * = p-value < 0.05, ns = not significant.

Figure 7| Aire⁺ ILC3s induce pro-survival program in candida-specific T_H17 clones

a) Volcano plot of bulk RNA-seq analysis showing differential gene expression in Aire⁺ ILC3s that were isolated from pLN of HKCA-stimulated *Aire*^{GFP}*Aire*^{+/+} vs *Aire*^{GFP}*Aire*^{-/-} mice. Dashed lines indicate the Fc=2.0 and p-value=0.05 cutoff. Selected genes are highlighted in blue (antigen cell adhesion, co-stimulation), red (cytokine and chemokine signaling), green (candida sensing receptors). **b)** Fold change:fold change (Fc:Fc) graph of RNA-seq data showing differential gene expression in Aire⁺ ILC3s promoted by HKCA stimulation. Comparison of fold-change of HKCA-stimulated vs. non-stimulated Aire⁺ ILC3s isolated from *Aire*^{GFP}*Aire*^{+/+} vs *Aire*^{GFP}*Aire*^{-/-} (x-axis) and Aire⁺ ILC3s from stimulated *Aire*^{GFP}*Aire*^{+/+} vs stimulated *Aire*^{GFP}*Aire*^{-/-} (y-axis). **c)** Volcano plot of RNA-seq data showing differential gene expression of *Rorc*-GFP⁺ versus non-proliferating OT-II T cells derived from WT (*Rorc*-Cre⁻*Aire*^{fl/fl}) versus ILC3^{ΔAire} (*Rorc*-Cre⁺*Aire*^{fl/fl}) mice. The mice were transferred with naïve OT-II CD4⁺ T cells and subsequently injected with HKCA-OVA four times during a single week; **d)** Volcano plot of RNA-seq data showing differential gene expression of *Rorc*-GFP⁺ OT-II T cells derived from WT versus ILC3^{ΔAire} mice treated as in **(c)**. Dashed lines indicate the Fc=2.0 and p-value=0.05 cutoff. Data are derived from three independent replicates. **(e)** RNA-Seq based heatmap showing the level of expression of selected genes in *Rorc*-GFP⁺ OT-II T cells isolated from WT and ILC3^{ΔAire} mice. Data are plotted as the z-score calculated

588 for particular row. (f) GO enrichment for upregulated differentially expressed genes from *Rorc*-
589 GFP⁺ OT-II T cells derived from WT versus ILC3^{ΔAire} mice.

MATERIAL AND METHODS

Mice

The Aire^{fl/fl} (Jax: 031409;³⁰), Aire^{-/-} (004743 C57BL/6J and 006360 NOD genetic background;¹ and⁵²), Aire-GFP (Aire-IGRP-GFP;⁵³) a kind gift of Dr. M. S. Anderson (University of California, San Francisco, USA), CD45.1 congenic strain (002014), CD90.1 congenic strain (000406), *Clec7a*^{-/-} (012337;⁵⁴), *Foxn1*-Cre (018448;⁵⁵), *Lgals3*^{-/-} (006338;⁵⁶), OT-II (004194;⁵⁷), *Rag1*^{-/-} (002216;⁵⁸) *Rorc*-Cre (022791;³¹), *Rorc*-GFP (007572;³¹), *Rosa*-tdTomato (007914;⁵⁹) strains were used in the study. Unless indicated otherwise, all mouse strains were of C57BL6/J genetic background and were purchased from Jackson laboratories if not indicated otherwise. Mice were housed in the premises of Weizmann Institute of Science in SPF conditions. All experiments were approved by local ethical committee (IACUC) under numbers: 39661117-2, 01420218-2, 04690718-2, 14850619-2. Usually, 6-8 weeks old mice were used for the experiments with the exception of bone marrow chimeras, where mice were 12-15 weeks old. For the generation of bone marrow chimeras, recipients were irradiated by single dose of 900 rad and transplanted by 1.10⁷ bone marrow cells. Only mice with reconstitution level higher than 95% were used for experiments. For the generation of CD90-disparate chimeras the protocol described elsewhere was used³⁴. Briefly, 6 weeks old *Rag1*^{-/-} mice were intravenously adoptively transferred by 8.10⁷ MACS-enriched T cells and B-cells from CD90.1 mice. These were let to homeostatically proliferate for two months. After this period, mice were intraperitoneally injected by 250µg of CD90.2 depleting antibody (BioXcell) every 3 days. Whenever possible, littermates were used as the controls.

Human samples

Patients were included from Norwegian National Registry of Organ Specific Autoimmune Diseases and fulfilled the APS-1 diagnostic criteria. All APS-1 patients suffer from *C. albicans* infection. Gender matched controls were recruited from the local blood bank at Haukeland University

Hospital. All participants gave informed and written consent, and the study was approved by The Regional Committee for Medical and Health Research Ethics for Western Norway. PBMC were obtained from the whole blood by centrifugation in Ficoll-Paque (GE Healthcare), freeze and stored in liquid nitrogen. The proliferation assay was done for all samples together; whole PBMC fraction ($5 \cdot 10^6$ cells) was stained by Cell proliferation dye and stimulated by $1 \cdot 10^5$ HKCA particles (Invivogen). Proliferative response was measured 4 and 6 days later.

Material

All material and reagents used in this study are described in particular relevant section and in detail specified in Suppl. Table 1 and 2.

Infection by live *C. albicans*

Experimental mice were intra-venously injected every two days by 10^6 particles of heat-killed *C. albicans* in PBS for the duration of three weeks. After this period, mice were infected by single dose of 10^5 particles of live *C. albicans*. Mice were then monitored daily for their well-being and were sacrificed when they lose 20% of their initial weight or show signs of distress.

Mucosal colonization by *C. albicans*

In order to establish the gastrointestinal colonization by *C. albicans*, mice were supplemented *ad libitum* by 1mg/ml of ampicillin in drinking water and were kept on it during the experiment. After two days, mice were colonized by 50 μ l of 10^6 particles *C. albicans* in PBS. The inoculation was performed dropwise into the mouth of mice. Experimental mice were monitored daily for their well-being.

816 **ELISA**

817 For the detection of autoantibodies, the ELISA microtiter plate was pre-coated by 5µl/ml of
818 recombinant IL-17 or IL-22 in bicarbonate buffer overnight in 4°C. The plate was washed and
819 blocked by 5% milk. Detection of autoantibodies was performed using anti-IgG specific antibody
820 conjugated to HRP (Jackson ImmunoResearch). For the detection of human IL-17A cytokine the
821 Human IL-17A ELISA kit (Biolegend) was used according to manufactures instructions.

822

823 ***C. albicans* strains and preparation of HKCA**

824 The wild-type *C. albicans* strain used in the study is of SC5314 origin⁶⁰. GFP and OVA coding
825 sequence were inserted in the coding frame after the c-terminal end of the Eno1 gene resulting in
826 generation of OVA-expressing strain derived from the wild-type⁶¹. Both strains were a kind gift of
827 Dr. Judith Berman (Tel Aviv University, Israel). *C. albicans* was grown in 30°C using YPD agar.
828 HKCA variant was prepared by heat-inactivation of the yeast in 60°C for one hour in thermo-
829 shaker. The heat-inactivation was tested by seeding the HKCA on YPD plates.

830

831 **Cell isolation for flow cytometry and cell sorting**

832 Aire-ILC3, MHCII-ILC3, ILC3s and DCs were isolated as described previously¹⁹. Although all
833 systemic LNs were found to contain Aire-ILC3 like cells¹⁹, for consistency most of the experiments
834 was done by analysis of cells and cellular responses in the popliteal LNs, unless stated otherwise.
835 Briefly, lymph nodes were collected and subjected to several rounds of enzymatic digestion by
836 Dispase I. (Roche). Single cell suspension was depleted of lineage positive cells using LS-column
837 based MACS enrichment by cocktail of biotinylated antibodies (TCR-β, CD3, CD19, B220,
838 CD11b, F4/80, Gr1, CD11c, Biolegend) and anti-biotin microbeads (Miltenyi Biotec). T cells were
839 isolated by meshing the skin-draining lymph nodes and spleens through 40 µm nylon mesh. For
840 surface staining, cells were incubated with antibodies for 25 minutes on ice. DAPI (Sigma) of

viability dye eF506 (eBioscience) were used for live/dead cells discrimination. For intracellular staining fixation the Foxp3 / Transcription factor staining buffer set (eBioscience) was used according to manufacturer's recommendation. Subsequently, intracellular targets were stained by antibodies for one hour in room temperature. Cells from the small intestinal lamina propria, oral cavity or esophagus were collected by enzymatic digestion. Briefly, small intestinal tissue was subjected to two rounds of epithelial cells removal by incubation with 2mM EDTA in HBSS for 20 minutes in 37°C. All the tissues were digested in 1mg/ml of Collagenase D and (Roche) for 1 hour and immune cells were enriched by Percoll gradient (Sigma Aldrich). For details concerning antibodies please refer to Suppl. Table 2. Flow cytometry analysis and cell sorting were performed using BD CantoII, LSRII and AriaIII machines (BD). FlowJO (V10; Tristar) software was used for flow cytometry data analysis.

RNA sequencing

Single cell suspensions were directly FACS sorted to Lysis/Binding buffer (Invitrogen) and frozen on dry ice. RNA was isolated using Dynabeads (Invitrogen) according to manufactures protocol. The MARS-seq protocol described elsewhere was followed to generate the sequencing libraries⁶². The sequencing of the library was performed using the NextSeq high output kit and NextSeq 500 sequencer (Illumina). Obtained data were analyzed for differential gene expression using the UTAP pipeline⁶³.

Imagestream analysis of endocytosis

Lineage negative cell population or enriched DCs were co-incubated in-test described time period together with Cell proliferation dye eF660 (Thermo) stained 10⁵/ml HKCA particles in 37°C. Cells were fixed by Foxp3 / Transcription factor staining buffer set (eBioscience) and stained immediately after the end of incubation period and subjected to Imagestream analysis (Amnis). Data were analyzed using Ideas (v6.2) software (Amnis).

Image acquisition by TPLSM

MACS-isolated tdTomato⁺ cells were adoptively transferred to *Aire*-GFP hosts and stimulated by heat-killed HKCA or HKCA-OVA. Zeiss LSM 880 upright microscope fitted with Coherent Chameleon Vision laser was used for lymph node imaging experiments. Images were acquired with a femtosecond-pulsed two-photon laser tuned to 930 nm. The microscope was fitted with a filter cube containing 565 LPXR to split the emission to a PMT detector (with a 579-631 nm filter for tdTomato fluorescence) and to an additional 505 LPXR mirror to further split the emission to 2 GaAsp detectors (with a 500-550nm filter for GFP fluorescence). Pictures were acquired at 512 × 512 x-y resolution and the zoom was set to 1.5.

Analysis of endocytosis and antigen presentation capacity by FACS

Experimental mice were intravenously injected by 10⁶ Cell proliferation dye eF660 (Thermo) stained HKCA. Mice were analyzed in indicated described time periods. For intravascular staining, mice were injected five minutes prior the analysis intravenously by 5 µg of anti-mouse CD45 BV605 monoclonal antibody (30-F11, Biolegend). For the antigen presentation assays experimental mice were intravenously injected by 10⁶ HKCA or HKCA-OVA particles. Cells with antigen presentation capacity were isolated using FACS-sort and incubated with DO11.10 TCR NFAT-GFP cell line⁴ for 17 hours in ratio 1:5. GFP-fluorescence was measured using FACS.

Adoptive T cell transfer and stimulation of mice by HKCA

Naïve ovalbumin specific TCR⁺ OT-II cells from CD45.1⁺ mice and wild-type derived CD4⁺ T cells (CD45.1/CD45.2) were isolated using Naïve CD4⁺ T cells isolation kit (Miltenyi Biotec), mixed in 1:1 ratio, stained by Cell proliferation dye eF660 (Thermo) and transfer via tail vein to recipient mice. Once in two days, mice were injected by 10⁶ HKCA or HKCA-OVA particles via tail vein.

Tetramer staining of *C. albicans* specific T cells

Als1 tetramers conjugated with PE and APC were used to detect *C. albicans* specific T cells from HKCA stimulated mice or mice after *C. albicans* colonization. The staining by tetramers and pulldown of tetramer positive cells by anti-PE and anti-APC conjugated microbeads (Miltenyi Biotec) was performed as described elsewhere⁶⁴. Each batch of tetramer reagent was titrated to determine the optimal staining concentration. We thank the NIH Tetramer Core Facility for providing tetramer reagents.

Isolation of DNA from tissue and intestinal content and quantification of *C. albicans* burden

Approximately 3mm of the ileum or kidney or liver tissue were surgically resected including its content. DNA was extracted using Quick-DNA kit (Zymo research) according to manufactures instructions. 10ng of isolated DNA was used for downstream quantitative PCR reaction using Syber -green (Roche) and following set of primers for detection of *C. albicans* (pF: TTTATCAACTTGTACACCAGA , pR:ATCCCGCCTTACCACTACCG) and bacterial ribosomal subunit 16S (pF: ACTCCTACGGGAGGCAGCAGT, pR: ATTACCGCGGCTGCTGGC) as the calibrator. The relative *C. albicans* DNA content in the samples was calculated using method described elsewhere⁶⁵.

Isolation of RNA from tissues and quantification of gene expression

Approximately 0.1g of the tongue tissue, esophagus, ileal part of small intestine and kidney was collected and RNA was extracted using Nucleospin RNA Mini kit (Macherey Nagel) according to manufactures instructions. Isolated RNA was subjected to reverse transcription reaction using RevertAid RT Reverse Transcription Kit (Thermo). Quantitative PCR reaction using Syber -green (Roche) and following set of primers was used; *Il17a* (pF: TGACCCCTAAGAAACCCCA, pR: TCATTGTGGAGGGCAGACAA), *Il17f* (pF: GAAGGCTGGGAAGTGTCTC , pR:

CGGAGTTCATGGTGCTGTCT), *Ii22* (pF: TTGACACTTGTGCGATCTCTGA, pR: AAAGGTGCGGTTGACGATGT), and *Casc3* as housekeeping gene (pF: TTCGAGGTGTGCCTAACCA, pR: GCTTAGCTCGACCACTCTGG). The relative gene expression was calculated using method described elsewhere⁶⁵.

Mouse model of Oropharyngeal candidiasis (OPC)

Mice were first primed by repeated injection of 10⁶ HKCA particles every second day for the duration of two weeks. Then, previously established protocol was followed³⁵. Briefly, mice were sedated and exposed to *C. albicans* orally for 1.5 hours using cotton swabs soaked with *C. albicans* diluted in PBS (10⁷ particles/ml). Mice were analyzed five days post oral inoculation.

Determination of *C. albicans* CFU

0.2g of the tongue, esophagus, ileal part of small intestine and kidney tissue was mechanically disrupted in PBS and plated on Sabouraud Dextrose Agar (Merck) in two dilutions. Number of colonies was calculated after 24 and 48 hours. The CFU were recalculated per g of original tissue.

Statistical analysis

Unless indicated otherwise, statistical significance was assessed using two-tailed Student's *t* test calculated in GraphPad Prism program. For summarizing the p-value, following marks were used: *** = p-value < 0.0001, ** = p-value < 0.001, * = p-value < 0.05, ns = not significant.

Access codes for all transcriptomics data

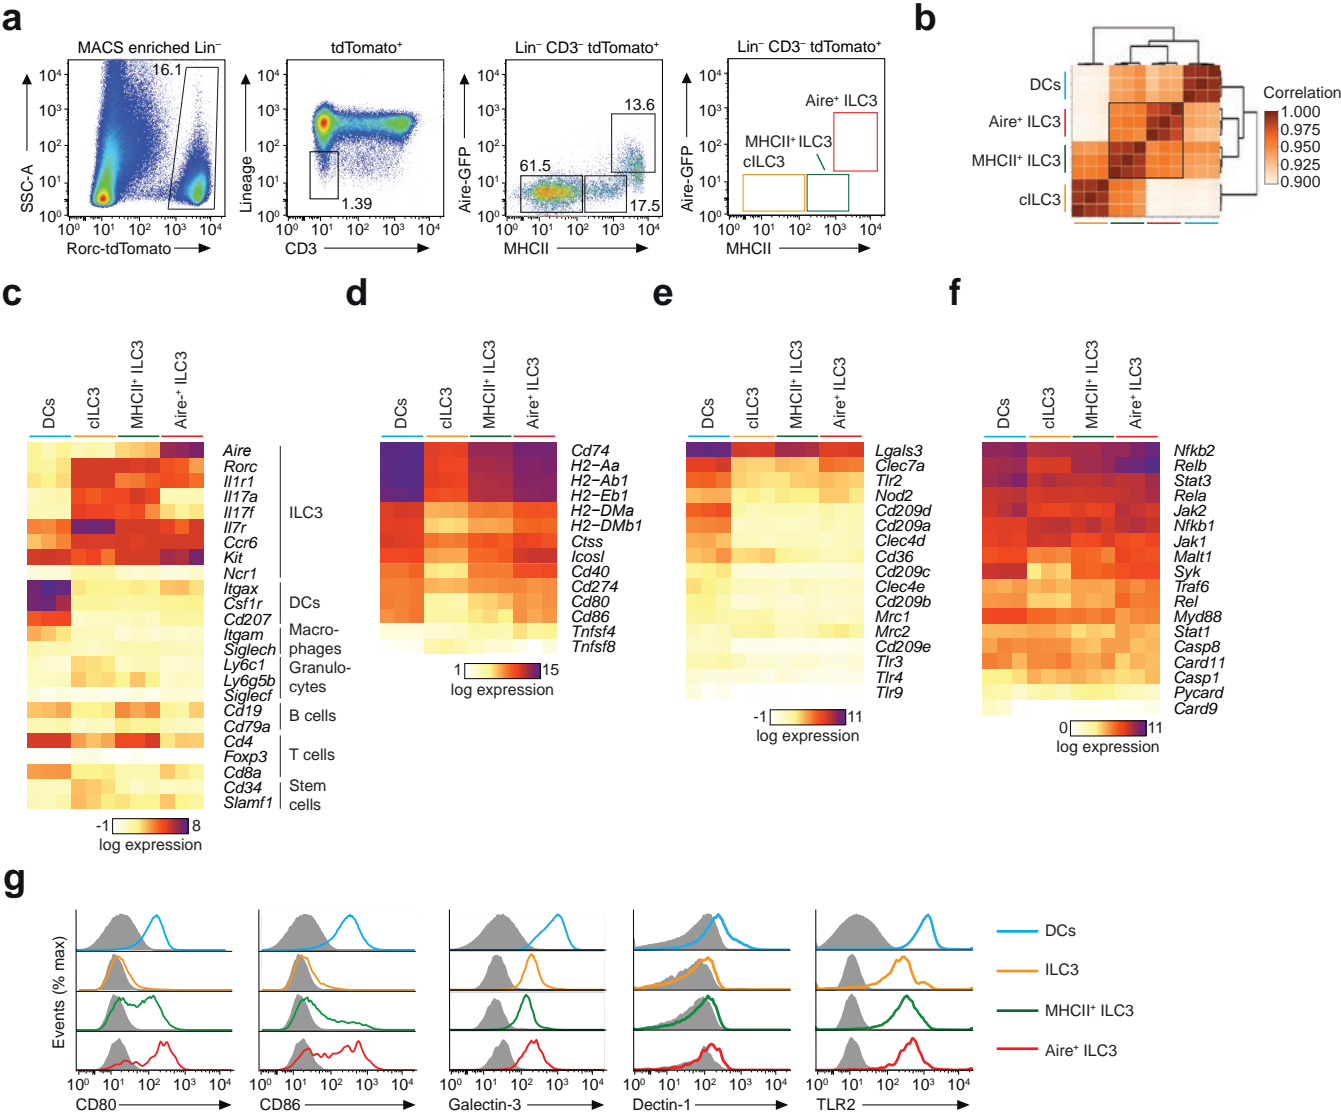

All RNA-seq data are available at GEO under accession number: GSE203158
